     A review with 22 refs. A technol. that shows great promise for treating
AB
     drinking water is to apply multiple disinfectants/oxidants. The anal.
     chem. methods needed to monitor and control treatment systems using
```

multiple oxidants have not been fully developed. A common problem

originates from the fact that many of the available methods are adaptations of chlorine methods and do not measure individual species, rather, the concn. of the various species are detd. by difference. When a disinfectant/oxidant is present in high concn., the existence of numerous intermediates is possible. These species are generally difficult to isolate and identify because of their rapid reaction and interactions. In certain cases, chem. masks can be used to improve the selectivity of an anal. method by isolating reactive species. Kinetic methods based on the reaction rate differences of oxidants with a reagent can also be used to identify and/or quantify multiple oxidant species.

TI Use of Lissamine Green B as a spectrophotometric reagent for the determination of low residuals of chlorine dioxide

AU Chiswell, Barry; O'Halloran, Kelvin R.

CS Dep. Chem., Univ. Queensland, St. Lucia, 4072, Australia

SO Analyst (London) (1991), 116(6), 657-61

AB A method for the spectrophotometric detn., using Lissamine Green B, of ClO2 in the presence of other Cl species, i.e., free Cl, ClO2-, chloramine and ClO3-, was developed. The method overcomes the major problem found with the commonly used N,N'-diethyl-p-phenylenediamine method for detd. ClO2, namely interference from free and combined Cl. The detection limit of the proposed method is 0.03 ± 0.01 ppm of ClO2; the calibration graph is linear in 0-0.5 ppm ClO2, and the method was verified by cyclic voltammetry.

TI Combined coulometric-spectrophotometric method for determining small quantities of free chlorine and bromine

AU Nikolic, Kosta; Velasevic, Ksenija

CS Zavod Fiz. Hem., Farm. Fak., Belgrade, Yugoslavia

SO Arh. Farm. (1986), 36(6), 279-81 CODEN: ARFMAC; ISSN: 0004-1963

AB A method for the detn. of small quantities of Br and Cl by using methyl orange is presented. Std. halogen solns. of known concns. were prepd. coulometrically by using electrogenerated Br and Cl in the anode compartment in the presence of properly chosen supporting electrolytes. Electrogenerated Br and Cl react with the azo group and thus methyl orange is decolorized. Since the reaction of halogen and methyl orange is quant., solns. of precisely known halogen concns. can be simply prepd. The method is practicable for the detn. of small quantities of Br and Cl, resp., in different solns.

AB A disposable plastic syringe contains a measured quantity of a water-sol. colorimetric reagent compn. proportioned to the vol. of a water sample which may be drawn into the syringe. The color produced in the water sample is compared to a chart std. which indicates the concn. of Cl in the water sample. The measured quantity of the reagent compn. is preferably applied as a dried printed spot to an inside surface of the syringe device. The app. is esp. useful in controlling the quality of water in swimming pools.

ANSWER 82 OF 107 CA COPYRIGHT 2001 ACS

AN 76:148440 CA

TI Simultaneous determination of bromide and chlorine with methyl orange

AU Laitinen, H. A.; Boyer, Kenneth W.

CS Dep. Chem., Univ. Illinois, Urbana, Ill., USA

SO Anal. Chem. (1972), 44(6), 920-6

The reaction between methyl orange and Br or Cl involves competition between aromatic ring substitution and azo link cleavage, both of which produce a large decrease in the molar absorptivity of the 505-nm methyl orange absorption peak. However, predominant ring substitution for the Br reaction produces an increase in absorbance at 317 nm, whereas predominant azo link cleavage for the Cl reaction produces a decrease in absorbance at 317 nm. By utilizing the changes in the v-visible spectra of methyl orange solns, upon reaction with gaseous mixts, of Br and Cl in N, both the total halogen content $\leq 5~\mu \rm equiv/l$, and individual halogen mole fractions were detd, with 8% relative error and \pm 11% relative std, deviation. The formation of BrCl limits the total halogen concn. that can be anal. distinguished to $< 5~\mu \rm equiv/l$, in N.

TI Critical study of different methods for determination of chlorite

AU Hashmi, M. H.; Ayaz, A. A.

CS Pakistan Council Sci. Ind. Res., Lahore

SO Anal. Chem. (1963), 35(13), 2194-5

AB Five methods were carried out with 0.01N KIO3 as the primary standard. (1) Hypochlorite (I) soln. was acidified after addn. of excess KI, let stand 5 min., and titrated with Na2S2O3. The titer included I and chlorite (II) ions. (2) A known amt. of Na benzenesulfinate (III) was titrated with standard I soln. using starch-iodide as external indicator. It was necessary to add 0.5 g. NaHCO3 and a small amt. of KBr for a distinct end

point with Bordeaux (IV) of tartrazine (V) as internal indicator. Small amts. of NaHCO3 and KBr were added to standard As2O3 soln., and the soln. was titrated with I soln. with V as indicator. The titer included only I ions. (4) A vol. of 10 ml. of I soln. and an excess (15 ml.) of 20% phenol soln. were mixed and let stand 5 min. Excess solid KI and 4N H2SO4 were added, and after 5 min. the soln. was titrated with Na2S2O3. vol. of 10 ml. of Na hypochlorite was buffered to pH 9.3 by H3BO3 and an excess of solid KBr added. After 45-60 sec., (NH4)2SO4 was added with continuous shaking, and after 10 min. excess KI and 4N H2SO4. The titer included II ions only. liberated I2 was titrated with Na2S2O3. The results indicate that III reacts with both I and II. The external indicators, IV and V, gave accurate results. The (NH4)2SO4 method (5) is as reliable for the detn. of II as the combination of As203 and Na2S203 (3 and The I ion is converted to hypobromite at pH 9-9.4 by KBr and is destroyed by (NH4)2SO4 leaving II ions. Phenol reacts with both I and II leaving a small amt. of available Cl.

TI Generation and use of chlorine dioxide in water treatment

AU Granstrom, Marvin L.; Lee, G. Fred

CS Rutgers Univ., New Brunswick, NJ

SO J. Am. Water Works Assoc. (1958), 50, 1453-66

AB The results of a questionnaire to users of ClO2 are discussed. The principal reasons for using ClO2 involve taste and odor problems in addn. to its replacing Cl as a disinfectant. Lowering the pH of the reaction while decreasing somewhat the yield of ClO2 from chlorite, slightly increases the rate of the reaction. The measurement of Cl and ClO2 are discussed.

ANSWER 106 OF 107 CA COPYRIGHT 2001 ACS

OKEF 41:6003i,6004a-c

TI Colorimetric determination of free chlorine with methyl orange

AU Taras, Michael

CS Dept. Water Supply, Detroit, MI

SO Anal. Chem. (1947), 19, 342-3

The reaction between free Cl and methyl orange occurs in the ratio of 2 mols. of free Cl to 1 mol. of dye. A colorimetric method for detg. free Cl, based on this mol. relation, is described. Directions for prepg. solns. and permanent standards are included. The method is sensitive to 0.10 p.p.m. Cl. Of the common lab. acids, only dil. HCl will support the reaction spontaneously. Near a pH of 3.0 the color of methyl orange ceases to vary with the acidity, and the resulting color is exclusively a function of the Cl content. Two drops (0.1 ml.) of 5 N HCl is usually sufficient to lower the pH to the optimum level when a 100-ml. vol. is employed. The reaction is independent of sample temp. Chloramine strengths conventionally encountered in water-works practice offer no trouble, but manganic ion above 0.05 p.p.m. causes interference. The methyl orange reagent is coequally sensitive to manganic ion and elementary Cl.
